C Prim's Problem

Time limit: 2s

Description

You are given a graph with $\boldsymbol{N}$ nodes and $\boldsymbol{M}$ bidirectional edges. Each edge has a positive integer weight. The edge connecting node u and node v is denoted by edge (u, v). This graph is connected, which means each node can reach all other nodes using one or more edges. This graph is simple, which means all edges connect two distinct nodes and each pair of nodes is connected by at most one edge.

Prim's algorithm on a simple connected graph runs as follows:

```
for each node u:
    cheapestCost[u] := INFINITY

unexplored := set of integers containing 1 to N
cheapestCost[1] := 0

while unexplored is not empty:
    u = element in unexplored with minimum value of cheapestCost
    // if there is more than one index in unexplored with minimum
    // value of cheapestCost, take the smallest index among those
    // indices.

    remove u from unexplored

    for each edge (u, v):
        // iterate all neighbours of node u
        if v is in unexplored:
            if weight of edge (u, v) < cheapestCost[w]:
                cheapestCost[w] := weight of edge (u, v)
```

You want to obtain a new graph by removing zero or more edges from the given graph. The new graph has to be connected. After running Prim's algorithm on the new graph, the value of `cheapestCost[u]` must be equal to `shortestPath[u]` for each node u, where `shortestPath[u]` is defined as the minimum sum of edge weights needed to be traversed to reach node u from node 1 on the new graph.

You want to find out the minimum number of edges that need to be removed so that the new graph satisfies the conditions above, or determine if it is impossible to do so.

Input

The first line contains two integers $\boldsymbol{N}$ and $\boldsymbol{M}$ separated by a space ($2 \leq \boldsymbol{N} \leq 100\,000$; $\boldsymbol{N} - 1 \leq \boldsymbol{M} \leq 200\,000$). The next $\boldsymbol{M}$ lines each contain three integers separated by spaces. The $i+1$-th

line contains integers $\boldsymbol{U}_i$, $\boldsymbol{V}_i$, dan $\boldsymbol{W}_i$ $(1 \le \boldsymbol{U}_i < \boldsymbol{V}_i \le \boldsymbol{N}; 1 \le \boldsymbol{W}_i \le 10^9)$ indicating edge i connects nodes $\boldsymbol{U}_i$ and $\boldsymbol{V}_i$ with weight $\boldsymbol{W}_i$. The given graph is a simple connected graph.

Output

The first line contains the minimum number of edges that need to be removed so that the new graph satisfies the conditions above, or -1 if it is impossible to do so.

Sample Input 1	Sample Output 1
3 2 1 2 10 1 3 100	0

Sample Input 2	Sample Output 2
3 2 1 2 10 2 3 30	-1

Sample Input 3	Sample Output 3
3 3 1 2 10 1 3 100 2 3 30	1

Explanation of samples

In sample input 1, running Prim's algorithm on the given graph produces `cheapestCost = [0, 10, 100] = shortestPath`. Therefore, the given graph already satisfies the conditions above, and you do not need to remove any edge.

In sample input 2, running Prim's algorithm on the given graph produces `cheapestCost = [0, 10, 30]`, but `shortestPath = [0, 10, 40]`. Removing any edge causes the new graph to be disconnected. Therefore, you cannot obtain any new graph satisfying the conditions above.

In sample input 2, running Prim's algorithm on the given graph produces `cheapestCost = [0, 10, 30]`, but `shortestPath = [0, 10, 40]`. By removing edge $(2, 3)$, you obtain a graph in sample input 1 as the new graph.
